Abstract

We reanalyzed 657 base pairs of mitochondrial cytochrome *b* (*cytb*) sequences of small five-toed jumboas *Scarturus* from Iran, which had been published as *Allactaga* by Mohammadi et al. (2016) in Zoology in the Middle East. We show that taxonomic names are available for the three main clusters they recognized: *S. hotsoni*, *S. elater*, and *S. toussi*. The last two species each contained two lineages, both in our analysis, as well as in those published earlier. We recommend the taxonomic identification of specimens in molecular analyses and call for deposition of voucher material in responsible public collections.

Main Text

Frequently, the initial step in biological research is identification in which a preexisting taxonomic name is assigned to the individuals of a given species. The name enables one to search for the existing information or to undertake comparisons with other organisms. Accurate species identification is crucial and misidentifications may have major consequences in basic and applied research (Bickford et al., 2007; Costa et al., 2015; Lourenço, 2016; Kryštufek et al., 2019; Taylor et al., 2019). Reference material, either in the form of museum vouchers or deposited nucleotide sequences, is frequently essential for accurate identification.

In a recent work, Mohammadi et al. (2016) readdressed the evolutionary history of small five-toed jumboas (*Allactaga* Cuvier, now *Scarturus* Gloger; see Michaux and Shenbrot, 2017) in Iran by using mitochondrial cytochrome *b* (*cytb*) marker. They identified five clusters which they either called lineages or clades. Because the nodes in their tree (Figure 2 in Mohammadi et al., 2016) lack information on statistical support, and genuine monophlyies are therefore unknown, we shall call them clusters. Mohammadi et al. (2016) concluded that (1) “the clear separation of the mtA lineage from the remaining specimens may suggest the occurrence of a new *Allactaga* species”, (2) the remaining clusters match subspecies of *A. elater* Lichtenstein, and (3) “*A. toussi* might not be a true species but instead a morphological variant of *A. elater*”. We found their taxonomic interpretation of small five-toed jumboas of Iran surprising and decided to repeat their analyses. We included in our assessment all *cytb* sequences used by Mohammadi et al. (2016). To these we added published sequences of *Scarturus elater*, *S. toussi*, *S. hotsoni* Thomas, *S. euphratica* Thomas, and *S. williamsi*

Thomas. A complete list of sequences with GenBank accession numbers and references appears in the Appendix. A number of these sequences, except those from Moshtaghi et al. (2016), are backed by museum vouchers housed in the Zoological Museum of Ferdowsi University of Mashhad, Iran (examined by the first author), Slovenian Museum of Natural History Ljubljana (Boris Kryšufek), General Commission for Scientific Agricultural Research, Damascus, Syria (now most probably lost; examined by Boris Kryšufek), and Department of Biology, Selçuk University, Konya, Turkey (determined by Professor Atilla Arslan). This allowed us to link with great confidence the haplotypes with existing taxonomic names.

Figure 1: Bayesian Inference tree summarizing phylogenetic relationships among 98 cytochrome *b* sequences representing all five-toed jerboas (*Scarturus*) from Iran and adjacent regions. All sequences were downloaded from GenBank (see Appendix for accession numbers). Sequences published by Mohammadi et al. (2016) are labeled as 'mtA' and 'mtB' and highlight in pink. Taxonomic names for lineages are on the right-hand side and follow Moshtaghi et al. (2016). The first and second numbers on the branches correspond to posterior probability (BPP) and bootstrap (BP) values in the BI and ML tree analyses, respectively.

Our phylogenetic analysis involved 98 *cytb* sequences (657 bp) and followed the protocol described in Moshtaghi et al. (2016). Bayesian Inference (BI) and Maximum Likelihood (ML) analyses gave trees of very similar topologies, therefore only the BI tree is shown in Figure 1. Small five-toed jerboas were in four major lineages which had strong support (BPP=1.0, BP \geq 0.88). All sequences from the cluster ‘mtA’ of Mohammadi et al. (2016) aligned with reference samples of *S. hotsoni* and the cluster ‘mtB’ emerged as identical with ‘*S. toussi* East’ of Moshtaghi et al. (2016). Furthermore, clusters 6 and 7 of Mohammadi et al. (2016) nested inside ‘*S. elater* 2’ and ‘*S. elater* 1’ of Moshtaghi et al. (2016), respectively. Therefore, the topology of Mohammadi’s et al. (2016) tree can be unambiguously interpreted with the existing body of taxonomic knowledge. Moreover, morphological examination of museum vouchers would equally ensure the application of proper taxonomic names, as *S. hotsoni* can be reliably distinguished from other small five-toed jerboas in southwestern Asia by its swollen bullae (Corbet, 1978). Although morphological differences between *S. elater* and *S. toussi* are less prominent, they are stable and allow safe classification of individuals (Darvish et al., 2008). For further phylogeographic structuring of *S. toussi* and *S. elater*, we direct the reader to Dianat et al. (2013), Moshtaghi et al. (2016) and Bannikova et al. (2018).

Palearctic mammals are among the best-known on the planet, and there is a solid foundation for studying their evolution and taxonomy. Despite this, it is imperative that any researcher gain important taxonomic knowledge on the group of interest before any work is undertaken. This should also involve the identification of specimens by traditional morphological characteristics which link modern phylogenetic analysis with the traditional Linnaean taxonomy (Schlick-Steiner et al., 2007).

Finally, we call for long-term preservation of vouchers and their deposition in responsible public collections to enable sound integrative taxonomic studies. Taxonomic results are crucial for species delimitation and all subsequent steps, like mapping distributional ranges, assessing risk for public health and planning conservation management.

Acknowledgements

This communication is dedicated to late Professor Jamshid Darvish who worked hard to disentangle the taxonomy of Iranian rodents in general and the jerboas in particular. Among other contributions, he also established the Zoological Museum of Ferdowsi University of Mashhad. We would like to thank Atilla Arslan for checking the identity of *Scarturus* deposited in the Selçuk University, Konya, Christiane Denys (Museum National d’Histoire Naturelle) for thoughtful comments on an earlier draft. Bruce D. Patterson (Field Museum of Natural History) is acknowledged for English editing.
